

Introduction

- Our combined model is a semi-naive Bayesian ranking method that combines naive Bayes with decision tables.
- Is a simple Bayesian network in which the decision table represents a conditional probability table.
- Can be viewed as a restricted version of Pazzani's semi-naive Bayesian model that finds one, rather than multiple, groups of dependent attributes.
- Has lower computational complexity that Pazanni's method.
- Search and evaluation is based on AUC.

• Empirical results show that the ranker resulting from our combined model, compared to either component technique, frequently significantly increases AUC.

Data Sets

Decision Tables (DT)

- Store the input data in condensed form based on a selected set of attributes.
- Is essentially a lookup table when making predictions. • Each entry in the table is associated with class probability estimates based on observed frequencies.
- Cross-validation is used to choose a set of discriminative attributes for the table.
- Cross-validation is efficient as the *structure* of the table does not change when adding or deleting instances. • In our experiments we used forward selection (guided by AUC) to select attributes for stand-alone decision
- tables.
- discretization.

Combining Naive Bayes and Decision Tables

Mark Hall¹ and Eibe Frank²

• Numeric attributes were discretized using MDL-based

Naive Bayes (NB)

- Simple and fast learner.
- Computes the posterior probability of a class using Bayes theorem.
- Probabilities for attribute values conditioned on the class are computed using frequency counts from the training data.
- Efficient under cross-validation as frequency counts can be updated in constant time.
- Numeric attributes were discretized using MDL-based discretization.
- In our experiments we used standard naive Bayes and a version that uses forward selection, guided by AUC, to select attributes (NB $_{AS}$).

Results: Mean AUC w/o attribute selection

•, • statistically significant improvement or degradation for DTNB

Combined Model (DTNB)

- Learning the combined model is similar to learning a decision table.
- At each step in the search:
- 1. Split the attributes into two disjoint subsets: one for the decision table, the other for naive Bayes.
- 2. Evaluate the merit of the combined model based on the split.
- We use a forward selection search where:
- At each step, selected attributes are modeled by naive Bayes and the remainder by the decision table.
- Initially, all attributes are modeled by the decision table
- Leave-one-out cross-validated AUC is used to evaluate the quality of a split based on the probability estimates generated by the combined model.

Results: Mean AUC with attribute selection

where:

Combined Model (DTNB)

• Combining class probability estimates from the decision table and naive Bayes:

 $Q(y|X) = \alpha \times Q_{DT}(y|X^{\top}) \times Q_{NB}(y|X^{\perp})/Q(y),$

 $-Q_{DT}(y|X^{\top})$ and $Q_{NB}(y|X^{\perp})$ are the class probability estimates obtained from the DT and NB respectively.

 $-\alpha$ is a normalization constant.

-Q(y) is the prior probability of the class.

• Probabilities are estimated using Laplace-corrected observed counts.

• We also consider a variant of the combined model that includes attribute selection (DTNB $_{AS}$).

Experiments

UCI data sets.

ulti-class data sets were converted to two-class data by merging all classes except the largest one.

runs of repeated holdout (66% training).

port mean AUC and standard deviation.

entical runs were used for each algorithm.

atistical significance computed from the corrected sampled t-test at the 5% level.

Conclusions

e combined model (DTNB) is a simple and effient semi-naive Bayesian ranking algorithm.

out attributes are split into two groups: one group igns class probabilities based on naive Bayes, the ner group based on a decision table, and the resultprobability estimates are combined.

pirical results show that:

DTNB performs well compared to stand-alone naive Bayes and decision tables. 11 significant wins against both, with two and one significant loss respectively. There are five cases where DTNB is significantly better than both.

When attribute selection is applied to both DTNB and naive Bayes there are seven significant wins for DTNB and only one significant loss.

Applying attribute selection to naive Bayes renders ts computational equal to DTNB (quadratic in the number of attributes).

Compared to standard decision tables, which have ouilt-in attribute selection, DTNB achieves 11 wins and no significant losses.
